WETLAND MAPPING & CLASSIFICATION

National Wetlands Inventory
Southwest Region
The National Wetlands Inventory (NWI) provides scientifically-based information on the location, status, extent, characteristics, and functions of wetlands and related habitats to promote the understanding and conservation of these resources.
Program Mission

The NWI program supports National and Service policies and initiatives to further conservation of the Nation’s wetlands and related habitats by;

1. Producing, maintaining, and providing current and historical geospatial wetland data and information for the Nation.

2. Analyzing and reporting on status and trends where wetlands and related habitats are vulnerable to change, loss or degradation, either man made or natural.

3. Promoting sound decision making and policy formation, through the development and dissemination of wetlands data and information through a variety of media.
The National Wetlands Inventory was established in 1974.

In 1986 The Emergency Wetlands Resources Act (P.L. 99-645) directed the USFWS to complete mapping of the Conterminous United States and Alaska.

The Cowardin Classification System used by the USFWS to describe wetland habitats is now the National Standard for any federally-based wetland mapping.

The Presidential; Office of Management and Budget (OMB) Circular A-16 states the USFWS is responsible for maintaining the wetlands data layer of the National Spatial Data Infrastructure (NSDI).
1970’s: Wetlands photo interpretation done on 1:120,000 and 1:80,000 B&W aerial photography. Wetlands coded out to *Class* only. Wetland delineations manually rectified to USGS topo base with Zoom Transfer Scope.

1980’s: Wetlands photo interpretation done on 1:58,000 and 1:40,000 CIR aerial photography. Wetlands coded to full extent of class system. Transfer rectification still done manually. Status and Trends work begins. Large-scale production of NWI maps ensues.

1990’s: Various scales and types of aerial photos are used as project areas become more focused, due to budget cuts and loss of primary contractor. Large-scale vectorization of NWI maps begins. Early attempts at digital map creation take place.

2000’s: “Pen & ink” era of NWI map creation ends. All data is created digitally, in a head’s-up or Digital Transfer Scope environment. NWI partners with USGS to create a Wetlands Master Geodatabase and web interface. National data standards are created for all digital NWI data.

2010’s: The onset of contributed and “scalable” data lead to near total completion of national wetlands dataset. EPA State and Tribal wetland programs account for much the this data inflow. Look for “NWI 2.0”.
Data Limitations

The Service's objective of mapping wetlands and deepwater habitats is to produce reconnaissance level information on the location, type and size of these resources. The maps are prepared from the analysis of high altitude imagery. Wetlands are identified based on vegetation, visible hydrology and geography. A margin of error is inherent in the use of imagery; thus, detailed on-the-ground inspection of any particular site may result in revision of the wetland boundaries or classification established through image analysis.

**Precautions** - Federal, state, and local regulatory agencies with jurisdiction over wetlands may define and describe wetlands in a different manner than that used in this inventory. There is no attempt, in either the design or products of this inventory, to define the limits of proprietary jurisdiction of any Federal, state, or local government or to establish the geographical scope of the regulatory programs of government agencies. Persons intending to engage in activities involving modifications within or adjacent to wetland areas should seek the advice of appropriate federal, state, or local agencies concerning specified agency regulatory programs and proprietary jurisdictions that may affect such activities.
What is a Wetland?

The Service uses the Cowardin et al. (1979) definition of a wetland; Classification of Wetlands and Deepwater Habitats of the United States (FWS/OBS – 79/31 December 1979). This definition is the Federal standard for classifying and mapping wetlands as determined by the Federal Geographic Data Committee. It is a two-part definition as indicated below:

Wetlands are lands transitional between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water.

For purposes of this classification wetlands must have one or more of the following three attributes: 1) at least periodically, the land supports predominantly hydrophytes; 2) the substrate is predominantly undrained hydric soil; and 3) the substrate is nonsoil and is saturated with water or covered by shallow water at some time during the growing season of each year.
Are Wetlands Important?

- Maintain Natural Fish/Wildlife Habitat
- Flood Control/Retention
- Promote Nutrient Transformation
- Carbon Sequestration
- Stream Bank Maintenance
- Water Quality
- Aquifer Recharge (other areas)
- Education/Recreation

One part of a bigger picture of ecosystem health… relating directly to human health.
Why Map Wetlands?

Create a current spatial inventory of wetland habitats;
  • Location
  • Area
  • Structure and Composition

Set a baseline for trend studies, future and past;
  • Human Development
  • Climate Change/Natural Variations
  • Restoration & Re-establishment
Why Map Wetlands?

Wetlands
Hydrography
Land Cover
Elevation
Jurisdiction
Etc…

One tool, in the toolbox of data and information systems to aid in making sound, scientific decisions.
Mapping Wetlands… The NWI Way!
Classification:
Wetland features classified using Cowardin Classification System

Identification:
Wetlands are identified and interpreted from digital aerial imagery
  • Vegetation
  • Hydrology
  • Soils

Digitization:
Wetland features created in a heads-up digital environment
  • Field surveys performed before/after to verify mapped wetlands
  • Data quality control and assurance procedures are integrated into all steps.

Mapping/Data Collection Process: Classification

Generalized Wetland Structure, Relating to Classification
Digital aerial imagery (publicly available) is used as a base for all wetland mapping.

In order to assure wetlands are accurately interpreted and identified, ancillary datasets are used to derive needed information;
- Hydrology/Topology (NHD, DRG’s, LiDAR)
- Soils (SSURGO)

Field surveys are conducted, before and after, the mapping process to verify wetland type and classification.

Wetland features are digitized using Esri, inc. ArcGIS, Geodatabase format. Polygonal and linear shapes are used to define wetland areas.
True color aerial image.
Field surveys are conducted to verify photo signatures.
Wetland features digitized, using Esri, Inc. ArcGIS.
Wetland features are attributed in data table.
Overview of wetland geospatial data (polygon and linear features).

Wetland Examples;

Emergent & scrub-shrub wetland (PEM1F & PSS1C).

Intermittent streambed with forested wetland (R4SBJ & PFO1J).
Wetland Examples;

Impounded pond, with adjacent emergent Wetlands (PUBHh & PEM1Fh).

Emergent wetland, former river channel (PEM1F).
Types of NWI Wetlands Data

Standard Wetlands Digital Data (Vector)
- Meets FGDC National Standards
- Photo interpreted, detailed mapping (0.1 acre)

Scanned Raster (from hardcopies)
- Scanned from original map mylar or photo overlay
- Rough geo-referencing
- Labels, leader lines, corner tic marks included

Hardcopy Only (1:24,000 scale)

Scalable Mapping
Landscape-level approach (small scale)
“Generalized” wetlands mapping
Truncated class system
Assembled from various data sources
May not meet National Map Standards
Types of NWI Wetlands Data
Scalable and Contributed Wetlands Data: “Filling in the Gaps”

Issues currently being faced by NWI/USFWS:

• Reduced Budgets
• Reduced Manpower
• Shifting Priorities
• Wetland Data Gaps
• Need for Landscape-level Data (LCC Support)
• Need to Cover Large Areas… Quickly!
Scalable Wetlands Data: “Filling in the Gaps”

Scalable maps are considered an interim product and may include map information at different scales, classification level(s), or resolution that are capable of being easily expanded or upgraded.

Scalable to ‘fill-in’ data gaps provide less detailed information
Scalable Wetlands Data: “Filling in the Gaps”

Source(s) Information
(utilizing existing databases)
- Hydrography
- Topology
- Other topographic map information
- Available imagery with limited analysis

Classification attributes
- Herbaceous wetland (emergent)
- Woody wetland (forested/shrub)
- Ponds
  - Impounded
- Lakes (lacustrine)
  - Reservoirs (impounded)
- Rivers
  - Lower perennial
  - Unknown perennial
  - Intermittent stream bed
Scalable Wetlands Data: “Filling in the Gaps”

Linear hydrology features buffered to create polygons and attributed to Cowardin classification.

Geospatial model creates topologically correct polygon feature class. This process is automated as an ArcGIS model.
Contributed Wetlands Data: “Filling in the Gaps”

Wetlands Data Produced/Funded from Outside Sources:

States (NM, AZ, WI, FL, NY, etc…)
Tribal (Navajo Nation, etc…)
Universities (Texas Tech)
NGO’s (Duck’s Unlimited)

Some State and Tribal projects were EPA-Funded.

Partnering w/ NWI/USFWS to meet National Wetland Mapping Standards.
Scalable and Contributed Wetlands Data: “Filling in the Gaps”
Scalable and Contributed Wetlands Data: “Filling in the Gaps”
SWI: Surface Waters & Wetlands Inventory: NWI 2.0

- Single composite database of landscape-level NWI wetland and surface water/hydrography data
- Assembled at a State-scale
- Seamless data layer, within and across state boundaries
- Complete ecological descriptions/Cowardin classification maintained
- Constructed for geospatial analysis/modeling
- Traceable water flow paths
U.S. Fish & Wildlife Service

SWI: Surface Waters & Wetlands Inventory: NWI 2.0
SWI: Surface Waters & Wetlands Inventory: NWI 2.0
SWI: Surface Waters & Wetlands Inventory: NWI 2.0
Addition of “Riparian” Data

The term “riparian” may be viewed from different perspectives, and has many definitions. In 1997, the western Regions of the Service developed a classification system to identify riparian areas that fell outside of the Cowardin et al. (1979) system. Since that time, “A System for Mapping Riparian Areas in the Western United States” (USFWS 2009) has also been adopted by the Service and is a national standard for riparian mapping, monitoring and data reporting as determined by the Federal Geographic Data Committee. The definition is indicated below:

Riparian areas are plant communities contiguous to and affected by surface and subsurface hydrologic features of perennial or intermittent lotic and lentic water bodies (rivers, streams, lakes, or drainage ways). Riparian areas have one or both of the following characteristics: 1) distinctly different vegetative species than adjacent areas, and 2) species similar to adjacent areas but exhibiting more vigorous or robust growth forms. Riparian areas are usually transitional between wetland and upland.
Applicability of “Riparian” Data

Riparian areas are plant communities contiguous to and affected by surface and subsurface hydrologic features of perennial or intermittent lotic and lentic water bodies (rivers, streams, lakes, or drainage ways).

Riparian areas are usually transitional between wetland and upland.
Importance of Riparian Habitats

- Greater than 75 percent of terrestrial wildlife species in the Great Basin region of eastern Oregon, as well as in southeastern Wyoming, are dependent on riparian habitats.

- In Arizona and New Mexico, 80 percent of all vertebrates use riparian areas for at least half their life cycles; more than half of these are totally dependent on riparian areas.

- 60 - 75 percent of Arizona's resident wildlife species depend on riparian areas to sustain their populations, yet these areas occupy less than 0.5 percent of the state's land area.

- Aquatic and fish productivity are directly related to a properly functioning and healthy riparian habitat (Washington Dept. Fish and Wildlife 1995).
